Page 16 Application No. 10/526,542 clean version of specification(description) (1)**Fixing member for a bicycle drive device**

The present invention relates to a universal fixing member for a device for driving of a bicycle wheel.

Driving systems for bicycles offer assistance for pedalling by means of an additional motor. This assistance generally consists of a drive mechanism arranged on one of the wheels of the bicycle. Thus the power of the motor drives the wheel and is added to the power exerted by the pressure on the pedals, which enables the cyclist to supply less effort.

Unlike the drive system illustrated in European Patent application EP-A-0.155.185, in addition to the familiar drive system the new invention introduces a technological innovation as regards the fixing of the drive device. The fixing member of the drive device comprises a single mounting connecting this element either, in the case of a bicycle, to the seat post or to the handlebars, or to the frame of another non-motorised vehicle. The said system is thus different since rather than being fixed permanently or in a non-adjustable manner to the frame of a non-motorised vehicle, this case provides a truly universe system.

The aim of the present invention is therefore to propose a member for fixing a device for driving a bicycle wheel, adapting easily to each type of vehicle.

Page 17 Application No. 10/526,542 clean version of specification(description)(2)

This aim is achieved by this member for fixing a device for driving, comprising

-a single fastener(7) connected either to the handlebars or the foot of the saddle, or to the frame of any bicycle or vehicle to be powered.

-the drive device being arranged so as to be able to pivot freely about an axis of the pivot(4),

this fixing member also comprising

-a first part (2), to which the drive device is connected so as to be able to pivot freely about the said axis of the pivot (4),

-a second part (5), which is connected to the first part so as to allow mutual adjusting between them together using two locking screws (19), the latter thus not being involved in the rotation of the power unit towards the wheel to be driven

Thus the drive device does not pivot directly with respect to the bicycle frame or to a part fixed with respect to this frame, but on the contrary with respect to an intermediate piece, referred to as the first part of the fixing member, whose angular position with respect to the second part can be adjusted in advance.

In conclusion, the drive device comprises both a preliminary adjustment system for a given vehicle and a system for putting it in contact with the wheel to be driven.

Page 18 Application No. 10/526,542 clean version of specification(description)(3)

The invention can be executed in at least three possible forms, namely:

For the first (figure 1), a sliding axle (19) in two curved slots (17) allowing widely variable adjustment of the two components of the universal arm (2) and (5) to a given angle.

For the second (figure 7), adjustment in fixed steps, determined by a series of holes arranged in an arc of a circle allowing a finite number of settings which are however more suitable for severe conditions.

For the third (figure 4), adjustment using a kneepiece for which the connection between parts (26) and (27) is executed using notches to be screw-fastened (6), supplemented by an extension comprising two elements of which one slides into the other and is set using a tightening pivot (25) which, as appropriate, will slide into the slots (24) or lodge in one of the locating holes which could be used instead of the slots referred to above.

Other embodiments of modular structures according to the invention are indicated in the accompanying claims. In addition, other details and particularities of the invention will emerge from the description given below, non-limitingly and with reference to the accompanying drawings.

In the drawings:

FIG. 1 is a schematic perspective view of an embodiment of a fixing member according to the invention.

FIG. 2 illustrates, in a side view, a fixing member according to the invention fixed to a first type of bicycle.

Page 19 Application No. 10/526,542 clean version of specification(description)(4)

FIG. 3 illustrates, in a side view, the fixing member according to FIG. 2 fixed to a second type of bicycle.

FIG. 4 is a perspective view of the first and second parts of a variant fixing member according to the invention.

FIG. 5 is a plan view of the connection between the two parts of the fixing member according to FIG. 4.

FIG. 6 depicts a side view of a detail of the construction of a variant second part of the fixing member.

FIG. 7 is a side view of yet another variant fixing member according to the invention.

In the drawings, the same reference number has been allocated to the same element or to a similar element.

If reference is made to FIG. 1, the fixing member (1) comprises a first part (2) connected to the drive device (3) so as to be able to pivot about an axis of the pivot(4). In addition, a second part (5) is attached to the first part (2), so as to allow their mutual adjusting about an adjusting and locking pivot (6). The second part also comprises a fastener (7) situated at a predetermined distance from adjusting and locking pivot (6).

This fastener (7) can comprise, for example, two blocks (8), the first block comprising a concave face (9) placed facing the concave face of the second block, and these blocks being connected by fixing means such as, for example, clamping screws (10). One of the blocks can be integral with the second part of the fixing member.

Page 20 Application No. 10/526,542 clean version of specification(description)(5)

In order to fix the fastener to a part of the handlebars, the operator can unscrew the clamping screws so as to separate the two blocks and place the block integral with the second part against the part of the bicycle to which the fixing member is fixed. Next, the operator can place the other block opposite and screw the clamping screws so as to fix the two blocks around the part of the handlebars. Likewise, the form of the sides of the blocks coming into contact with the bicycle can vary so as best to follow the circumferences of the place to which the fastener will be fixed.

It can also be imagined that the fastener can itself be connected detachably to the second part (5) of the fixing member. It can also be conceived, for example, that, as illustrated in FIG. 6, the fastener be supported on the second part (5) by a pivot (29), for adapting the position of the fastener in the most appropriate fashion to the element to which the fixing member must be attached. In the embodiment illustrated, the pivot (29) is formed by one of the clamping bolts of the fastener (7).

In the embodiment illustrated in FIGS. 1 to 3, the drive device is composed of a motor (21), for example electric, connected to a drive wheel by a transmission means, not shown, such as a chain or belt, the drive wheel acting on the tyre by communicating its movement to it.

In addition, the first part (2) of the fixing member can comprise a series of holes (12) close to the drive device. These holes represent various pivot seats or the swinging mounting, and for a system described in detail in patent EP 1593593. They allow an additional adjustment for the placing of the drive device. This is because these holes make it possible to modify the location of the axis of the pivot (4) so that the driving device can be positioned optimally.

Page 22 Application No. 10/526,542 clean version of specification(description)(7)

In addition, in FIGS. 1 to 3, the fixing member also comprises adjustment means (16) which comprise, on one of the parts of the fixing member, for example on the second part (5), at least one first orifice (17) extending in an arc of curvature having as its centre the adjusting and locking pivot (6) and a second orifice 18, for example situated on the first part 2 of the fixing member. In addition, a holding and clamping means is arranged so as to engage in the first orifice (17) and in the second orifice (18) in order thus to keep the two parts integral with each other, after clamping. In this case, the holding means (19) comprise a screw, a brace, two washers, and a self-locking nut.

As illustrated in FIGS. 2 and 3, the fixing member can adapt to various configurations. Thus, as depicted in FIG. 2, the fixing member makes it possible to attach the drive device to any form of handlebars or seat post of a bicycle or on part of the frame of another vehicle. It is also possible, as depicted in FIG. 3, to attach the fixing member onto handlebars, regardless of their configuration.

So as to adjust the pivot angle of the first part with respect to the second, the user makes the second part (5) and the first part (2) of the fixing member pivot mutually about the adjusting and locking pivot (6). Next, in the appropriate angular position, the fixing means (19), in this case a nut and a screw, are tightened in such a way that the first part is pressed against the second, thus fixing them solidly.

In addition, the drive device can comprise a shell provided with a luggage holder (20), the luggage holder preferably being arranged so as to carry a bag deposited so as to straddle the luggage holder. The bag can comprise also two locations, each arranged to contain for example batteries supplying the motor of the drive device. When the bag is placed straddling the luggage holder, the batteries will be placed so as to balance the weight on each side of the drive device.

THE PRESENT INVENTION IS ALSO APPLICABLE, BETWEEN THE FIRST PART AND THE SECOND PART OF THE DEVICE, a combination, not illustrated, of a first part (2), of the telescopic type similar to that illustrated in FIG. 4, and a second part (5) with rotary adjustment similar to that illustrated in FIG. 7.
